

Investigate the R implements of mean, median, standard deviation, variance, correlation, and covariance.

Mean

It is calculated by taking the sum of the values and dividing with the number of values in a data series.

The function `mean()` is used to calculate this in R.

Syntax

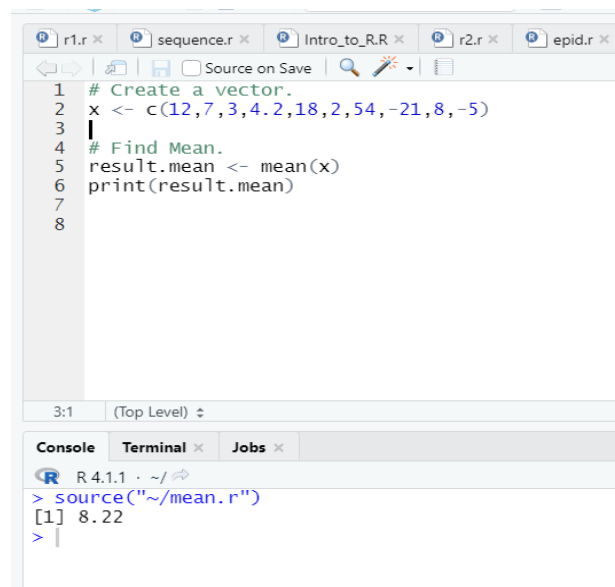

The basic syntax for calculating mean in R is –

`mean(x, trim = 0, na.rm = FALSE, ...)`

Following is the description of the parameters used –

- `x` is the input vector.
- `trim` is used to drop some observations from both end of the sorted vector.
- `na.rm` is used to remove the missing values from the input vector.

Example :

```
1 # Create a vector.
2 x <- c(12,7,3,4.2,18,2,54,-21,8,-5)
3 |
4 # Find Mean.
5 result.mean <- mean(x)
6 print(result.mean)
7
8
```

Console Terminal Jobs

R 4.1.1 · ~/

```
> source("~/mean.r")
[1] 8.22
> |
```

Median

The middle most value in a data series is called the median. The `median()` function is used in R to calculate this value.

Syntax

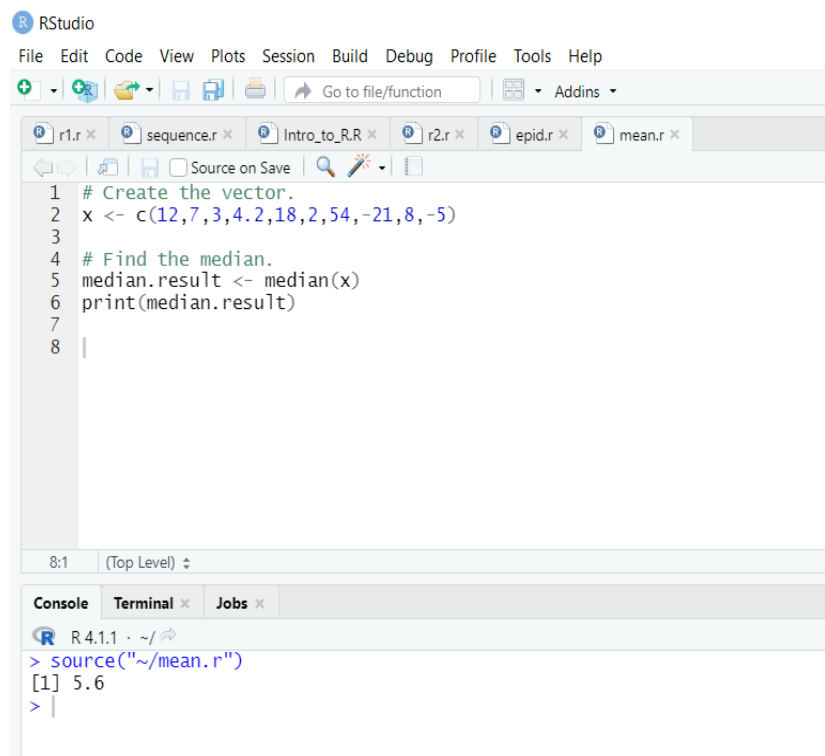

The basic syntax for calculating median in R is –

median(x, na.rm = FALSE)

Following is the description of the parameters used –

- x is the input vector.
- na.rm is used to remove the missing values from the input vector.

EXAMPLE

```
RStudio

> |
```

Mode

The mode is the value that has highest number of occurrences in a set of data. Unlike mean and median, mode can have both numeric and character data.

R does not have a standard in-built function to calculate mode. So we create a user function to calculate mode of a data set in R. This function takes the vector as input and gives the mode value as output.

EXAMPLE:

```
1 # Create the function.
2 getmode <- function(v) {
3   uniqv <- unique(v)
4   uniqv[which.max(tabulate(match(v, uniqv)))]
5 }
6
7 # Create the vector with numbers.
8 v <- c(2,1,2,3,1,2,3,4,1,5,5,3,2,3)
9
10 # Calculate the mode using the user function.
11 result <- getmode(v)
12 print(result)
13
14 # Create the vector with characters.
15 charv <- c("o","it","the","it","it")
16
17 # Calculate the mode using the user function.
18 result <- getmode(charv)
19 print(result)
20
21
```

```
R 4.1.1 · ~/
> source("~/mean.r")
[1] 2
[1] "it"
>
```

Standard Deviation

sd() Function

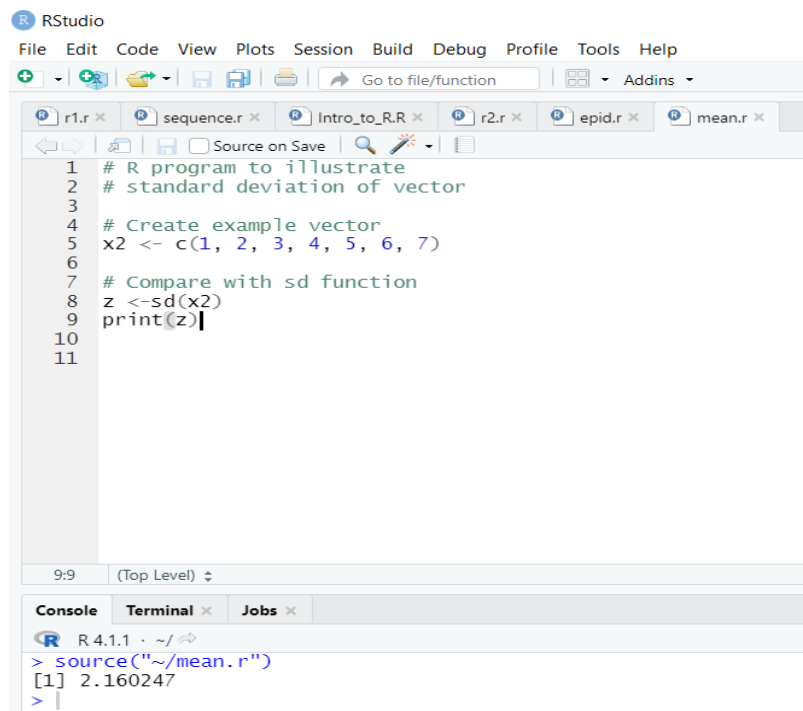

sd() function is used to compute the standard deviation of given values in R. It is the square root of its variance.

Syntax: sd(x)

Parameters:

x: numeric vector

EXAMPLE

RStudio

File Edit Code View Plots Session Build Debug Profile Tools Help

sequence.r x Intro_to_R.R x r2.r x epid.r x mean.r x

```
1 # R program to illustrate
2 # standard deviation of vector
3
4 # Create example vector
5 x2 <- c(1, 2, 3, 4, 5, 6, 7)
6
7 # Compare with sd function
8 z <- sd(x2)
9 print(z)
10
11
```

[1] 2.160247
> |
```

VARIANCE

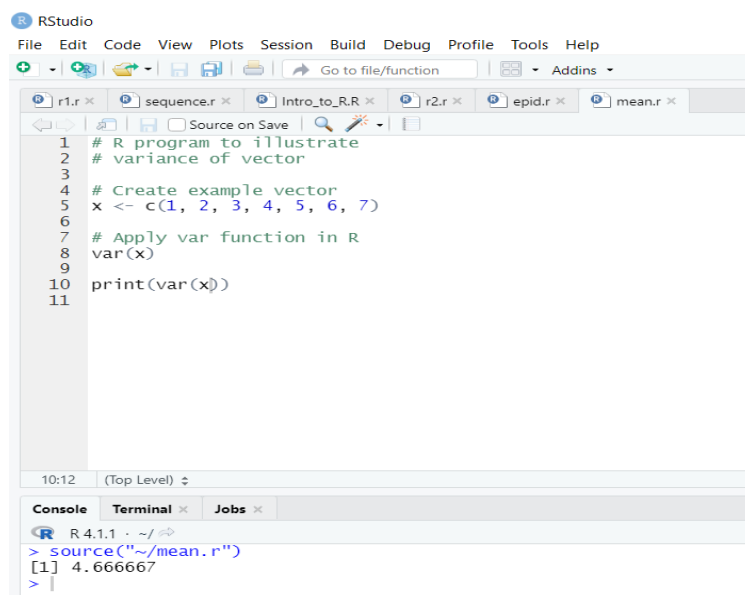

var() function in R Language computes the sample variance of a vector. It is the measure of how much value is away from the mean value.

Syntax: var(x)

Parameters:

x : numeric vector

EXAMPLE:

RStudio

[1] 4.666667
> |
```

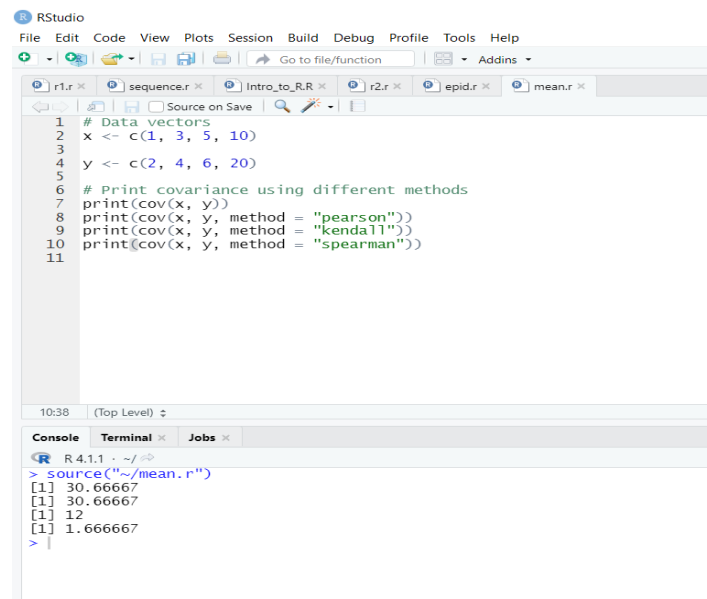

Covariance

In R programming, covariance can be measured using `cov()` function. Covariance is a statistical term used to measure the direction of the linear relationship between the data vectors.

Syntax: `cov(x, y, method)`

where,

- `x` and `y` represent the data vectors
- `method` defines the type of method to be used to compute covariance. Default is “pearson”.

```
RStudio
File Edit Code View Plots Session Build Debug Profile Tools Help
sequence.r Intro_to_R.R r2.r epid.r mean.r
1 # Data vectors
2 x <- c(1, 3, 5, 10)
3
4 y <- c(2, 4, 6, 20)
5
6 # Print covariance using different methods
7 print(cov(x, y))
8 print(cov(x, y, method = "pearson"))
9 print(cov(x, y, method = "kendall"))
10 print(cov(x, y, method = "spearman"))

```

Correlation

Syntax: `cor(x, y, method)`

where,

- `x` and `y` represent the data vectors
- `method` defines the type of method to be used to compute covariance. Default is “pearson”.
